TITLE: Study of some radiation defects in metals by measuring internal friction and modulus of elasticity

SOURCE: AN SSSR. Institut metallurgii. Vnutrenneye treniye v metallakh i splavakh (Internal friction in metals and alloys). Moscow, Izd-vo Nauka, 1966, 76-82

TOPIC TAGS: metal analysis, internal friction, elastic modulus, radiation damage, irradiation, *nuclear reactor core / RFT reactor core, IRT-1000 reactor core*

ABSTRACT: Samples of pure (99.98%) copper, molybdenum and tungsten were irradiated in the operating channel of an RFT reactor core at a flux of 10^{20} neutron/cm² and in the channel outside an IRT-1000 reactor core at a flux of 10^{14} neutron/cm². Internal friction (Q^{-1}) was measured between stresses of 1-1,000 G/mm² with maximum stress amplitude (σ) calculated according to the amplitude of vibrations; change of modulus of elasticity (E), associated with change of Q^{-1} to σ , was studied with respect to change of natural frequency vibrations squared (f^2) of sample in relation to σ . For copper, σ_{crit} rose 100 times after irradiation at 10^{20} neutron/cm² and Q^{-1} decreased by about 40% with respect to its pre-irradiation values. Changes in

10 3

Q^{-1} and σ_{crit} are explained by reaction of dislocations with spot defects at low neutron dosages, and reaction of dislocations with more complex defects (such as vacancy complexes) at high neutron dosages. This behavior differs from that of Mo and W in that Q_{min}^{-1} for Cu at a flux of 10^{20} neutron/cm² decreases while Q^{-1} for both Mo and W increases because these two metals have "free" (unattached to dislocations) spot defects which are absent in Cu. The increase of σ_{crit} for Mo and W may signify that dislocations, such as in Cu, are locked in place by radiation defects. A small increase in σ_{crit} for these metals is associated with the fact that many of the defects formed remain in the lattice because of low mobility of radiation defects in these metals in comparison with the same mobility in copper. Examination of change of modulus of elasticity for the metals under scrutiny showed that neutron irradiation may cause an increase or decrease in elastic modulus (E) for copper in relation to the magnitude of the integrated flux. This E for copper increases with small doses and decreases for large doses. Explanations for changes in modulus of elasticity are quite similar to those for changes in internal friction. Low temperatures, and other forms of radiation (gamma-rays, electrons), can be used to study spot defects by the internal friction method. Orig. art. has: 2 figures and 2 tables.

TITLE: Determination of the burnup of the fuel element of the icebreaker "Lenin" from the Cs-137 activity without chemical separation

SOURCE: Atomnaya energiya, v. 21, no. 2, 1966, 92-96

TOPIC TAGS: reactor fuel element, cesium, uranium compound, enriched uranium, reactor neutron flux, gamma neutron reaction

ABSTRACT: The authors determined the distribution of the burn-up along the length of the fuel element by measuring the intensity of the 0.66-Mev gamma lines of the Cs^{137} in the reaction products with a scintillation γ spectrometer with resolution 10--12%. The fuel element tested was made of uranium dioxide with 5.5% enrichment, operated for 428 effective days, and stored for 575 days after removal from the reactor. It was cut in the hot chamber in 11 places and two samples of the uranium dioxide were chosen from each cut. The activity was measured with a scintillation counter in a specially designed pickup (Fig. 1) and the data were processed with a pulse-height analyzer (AI-100) provided with a special information extraction system (VD) developed at the Institute of Atomic Energy im. I. V. Kurchatov by M. P. Sokolov. The calibration of

the apparatus and the processing of the results are described, and the integral flux of the thermal neutrons and the burnup rate are calculated. It is concluded that the method can be used to determine the relative distribution of the burnup, after suitable cooling of the fuel element with accuracy $\pm 6\%$ and the absolute burn-up value with accuracy $\pm 16\%$. The authors thank N. M. Mordvinov for a discussion of the results, and A. A. Markov and M. P. Sokolov for practical aid in preparing the system for information extraction. AUTHOR: Vikhrov, G.P.

TITLE: A Transistorized Universal Electronic Counter

PERIODICAL: Izmeritel'naya tekhnika, 1959, Nr 11, pp 49-52

ABSTRACT: The author describes an electronic counter with a capacity of $10^{-5} \div 1$. The block diagram of this transistorized counter is shown in Fig 1. The device was designed for measuring frequencies ($10^{-5} \div 1.5 \cdot 10^5$ cps) and time intervals ($10^{-4} \div 10^5$ sec), and electrical signals with an error below $\pm 2 \cdot 10^{-5} \pm 1$ count. Frequency measurements are reduced to counting the number of pulses, equal to the number of cycles of the input signal, during a time interval which is known with sufficient accuracy and which is determined by a quartz oscillator. The author describes in detail the different possible operating conditions. A control circuit is used for checking the accuracy of the counter. One of the most important parts is the conversion unit which converts the binary counting system

Card 1/2

SOV/115-59-11-22/36

A Transistorized Universal Electronic Counter

with a factor $K = 16$ to the decade system with a counting factor of $K = 10$. The principal circuit arrangement of this unit is shown in Fig 3. It consists of four binary cells. Each cell is a conventional transistorized trigger circuit with P13A transistors. In the so-called "cycle generator" P201 and P13 transistors are used. The shaping unit is composed of P-13 transistors. It converts input signals of any shape to pulses with the required stable parameters. This unit is composed of Schmitt trigger circuits and functions similar to a vacuum tube trigger circuit. The electronic counter is 440x180x195 mm and has a weight of 8 kg. It has a power consumption of only 0.5 watts and may be used in laboratories and under field conditions. Engineers A.A. Avizhen', K.I. Sakalauskas, A.A. Chervyakov, L.Ya. Kovaleva and S.A. Yushka participated in the development of the counter. There are 1 block diagram and 2 circuit diagrams.

AUTHORS: Pravdyuk, N. F., Pokrovskiy, Yu. I., Vikhrov, V. I.

TITLE: Effect of neutron bombardment on the internal friction of
monocrystalline and polycrystalline zinc

PERIODICAL: Atomnaya energiya, v. 10, no. 4, 1961, 347-352

TEXT: N. F. Pravdyuk has already reported in a lecture (Second Atomic Conference at Geneva 1958) about investigations of internal friction and of the critical amplitude of the maximum tension σ_{cr} before and after neutron bombardment of metals, and also of the influence of the orientation of the basal plane (0001) to the longitudinal axis of monocrystalline zinc. The method and equipment used have also been described there. This paper publishes additional results which have been obtained with monocrystalline and polycrystalline zinc. (σ_{cr} is that value of the maximum tension amplitude, at which internal friction starts to be a function of the tension amplitude). The monocrystalline specimens showed the following orientations of the (0001) planes to the longitudinal axis: 15, 40, 66, 76, 86, and 88°;

X

Effect of ...

specimens with 15, 40, 76, and 86° orientation have been exposed to neutron radiation. The internal friction has been measured at transverse oscillations (300 cps) before and after neutron bombardments having integral fluxes of $3 \cdot 10^{18}$ and $1.5 \cdot 10^{19}$ n/cm² and at a ratio of fast to thermal neutrons of 1 : 10. The amplitude of the maximum tension has been calculated from the oscillation amplitude. The results are represented graphically. Fig. 1 shows the change of internal friction as a function of the tension amplitude of non-irradiated monocrystalline zinc at angles θ given above the curves; the figures given below are the values of σ_{cr} .

Fig. 2 shows the same for neutron-bombarded ($3 \cdot 10^{18}$ n/cm²) monocrystals. Fig. 4 shows the change of the minimum internal friction of monocrystalline zinc as a function of the angle θ , and Fig. 5 shows the functions $\sigma_{cr}(\theta)$ -

both for monocrystals before and after bombardment. The following numerical values have been obtained:

σ_{cr}	15°	40°	66°	76°	86°	88°
before bombardment	105	20	40	120	400	600
after bombardment ($3 \cdot 10^{18}$ n/cm ²)	200	100	-	200	500	-
after bombardment ($1.5 \cdot 10^{19}$ n/cm ²)	350	280	-	-	550	-

Card 2/9

Effect of ...

S/089/61/010/004/003/027
B102/B212

The theoretical value is given as $\sigma_{cr} = 2\tau_{cr}/\sin 2\theta$, where $\tau_{cr} = \sigma_{cr} \cos \varphi \sin \theta$; τ denotes the tangential stress given by $(P/A)\cos \varphi \sin \theta$; and $P/A = \sigma_{cr}$. The notations are shown in Fig. 6: θ denotes the angle between the line of application of the force and the glide plane; φ represents the angle between the direction mm of a possible displacement in the glide plane and the axis of the specimen; nn denotes the normal on the glide plane. It has been found that the value of σ for bombarded specimens may be connected to the start of shift of dislocations along the basal plane. Fig. 7 shows $1/Q = f(\sigma)$ for non-irradiated (1) and irradiated (2) polycrystalline zinc; the irradiation has been done with $3 \cdot 10^{18}$ n/cm². The experimental curves are discussed in detail. One may imagine that the curves $1/Q = f(\sigma)$ consist of three sections: 1) $\sigma < \sigma_{cr}$; 2) $\sigma > \sigma_{cr}$; 3) $\sigma \gg \sigma_{cr}$.

The first two sections are the parts with reproducible internal friction, and the third one is that with irreproducible friction. The authors thank S. T. Konobeyevskiy for discussions. There are 7 figures, 1 table and 1 Soviet-bloc reference.

AUTHOR: Vikhrov V.I., Maj.Gen. of the Air Force

TITLE: The Stalingrad Battle (V bitve pod Stalingradom)

PERIODICAL: Vestnik Vozdushnogo Flota, 1957, Nr 10, pp. 30-36
(USSR)

ABSTRACT: In the summer campaign of 1942, the German command concentrated about 240 divisions against Soviet army, the main bulk of which was operating on the Stalingrad direction. The main grouping of these forces included: the 6th field army, 4th tank army, and the 4th air fleet (containing 1200 aircraft i.e. nearly half of the whole German air force). Thus, the enemy succeeded to concentrate considerable numerical superiority in forces and technical combat means.

Card 1/4

86-10-21/44

The Stalingrad Battle (Cont.)

Despite this superiority, the Soviet army was able to hamper the enemy movements and to gain the time necessary for preparation of counteroffensive. The Soviet 62nd army, under the command of Gen Chuykov, was defending the Stalingrad front. The Soviet aviation participated in defense of Stalingrad under extremely difficult conditions. The enemy by filling up constantly his losses, was able to maintain at the Stalingrad front 2-3 times superior air force (800-1000 aircraft). The Soviet command, preserving its aviation forces, used them only for the most decisive operations. Taking into consideration the numerical inferiority of the Soviet aviation, there was developed a special tactic of the aviation night operations, which was harassing the enemy relentlessly and many times succeeded to frustrate his offensive preparations. During the day the Soviet bombers operated from high altitudes and the shтурмовики from the medium heights, thus reducing the possibility of losses from the German fighters. At that period

Card 2/4

86-10-21/44

The Stalingrad Battle (Cont.)

Soviet pilots applied new air tactics for instance, attack of shturmoviks on a closed circle. During the Stalingrad battle the control of air combat became perfected thanks to a larger use of radio communications from the ground to pilot and vice versa. The first radio control post together with aviation division command station was installed in August 1942 at the North outskirts of Stalingrad. Thus the divisional commander was able to conduct the air combat and guide his pilots. Already, in September 1942, at the Stalingrad front the Soviet aviation established a reliable radiocommunication network, observation, early warning, communication and guidance system. Only in the second half of October 1942 in the region of Burkovskiy the fighters were called by radio from their airfield 95 times and 125 times they were radio guided against the enemy bombers. During 20 days of combat 315 enemy aircraft operations were destroyed, mostly fighters. Gradually, at the Stalingrad front the initiative in the air combat was wrested from the enemy. The fighter command received new types of aircraft: Yak-7 and La-5 equal in combat qualities to those of the enemy. Finally, during the Soviet

Card 3/4

The Stalingrad Battle (Cont.)

86-10-21/44

counter offensive at the Stalingrad front the Soviet aviation was active in destruction of encircled German grouping and frustrated the German plan of air evacuation of the encircled troops. The German 330,000 strong army was liquidated on the banks of the river Volga. In this great victory the Soviet aviation got a very important share.

Condensation of alcohols with aromatic hydrocarbons in the presence of anhydrous aluminum chloride. III. Condensation of primary alcohols with benzene and toluene. I.P.Tsukervanik and G. Vikhrova. J. Gen. Chem. (U.S.S.R.)

the condensation of secondary cyclic alcohols with aromatic hydrocarbons proceeds by intermediate cleavage of H_2O with the formation of cycloalkenes and cycloalkyl chlorides: $C_6H_5OH + AlCl_3 \rightarrow C_6H_5 + AlCl_2OH + HCl$; $C_6H_5 + HCl \xrightarrow{AlCl_3} C_6H_5Cl$; $C_6H_5 + C_6H_5 \xrightarrow{AlCl_3} Ph-C_6H_5$; $C_6H_5 + C_6H_5Cl \xrightarrow{AlCl_3} Ph-C_6H_4-C_6H_5 + HCl$. C. B.

laurel (identified as $m-C_6H_4(CO_2Me)_2$, m. 102°) and $sym-C_6H_4(C_6H_5)_2$, m. 108°, identified as tri-Me trimaleate, m. 144°. PhMe is less reactive, requiring more $AlCl_3$ and a large excess of PhMe. C_6H_5OH (70 g.), 50 g. $AlCl_3$, and 200 cc. PhMe gave 72% of a fraction, b.p. 254-60°, d_4^{20} 0.9343, n_D^{20} 1.5242, $M. R.$ 57.05, consisting of p - and m - $MeC_6H_4C_6H_5$, identified as p - and m - $C_6H_4(CO_2Me)_2$, resp., and 18% $3,5$ - $Me_2C_6H_3(C_6H_5)_2$, m. 93.5°, identified as tri-Me trimaleate. From the decompos. of C_6H_5OH with $AlCl_3$ with the formation of 18-20% C_6H_5 and 20-35% C_6H_5Cl it is assumed that by analogy with tertiary alcohols

806. CHEMICAL INVESTIGATION OF THE ANTIBIOTIC ACTINOXANTHINE.
I. INVESTIGATION OF THE METHODS OF SEPARATION AND CHEMICAL
PURIFICATION OF ACTINOXANTHINE (Russian text) - Vikhrova N.
M., Kryuchkova T.I., Preobrazhenskaya E.V. and Khor-
ntova A.S. Antibiotics Inst., Moscow - ANTIBIOT. 1957, 1 (21-24) illus. 2
The culture fluid of actinomyces 1131 inhibits growth of Ehrlich's adenocarcinoma.
It acts also on *M. pyogenes aureus*. Extraction of the antibiotic was obtained prin-
cipally by adsorption. Activated charcoal, permutit, silicagel, bentonite, infusor-
ia earth, aluminium oxide and synthetic ion-exchange resins (cationic and anionic)
were used for adsorption. After adsorption on charcoal it was not possible to find
a satisfactory method for desorption. Much better results were obtained with al-
uminium oxide adsorption. Chromatographic purification of the antibiotic on the
aluminium oxide column produced 4 layers: dark-brown, light-coloured, orange
and a lower adsorbent part. The antibiotic is mostly in the orange layer, and the
by-products in the brown layer. The culture fluid was treated successively with 3
portions of the adsorbent under static conditions. The first portion of the adsor-
bent adsorbs 50% of by-products, 2nd and 3rd portions 25 to 28%. Eluates were 4
to 6 times more active than culture fluid but they contained a large amount of diffi-
culty separable inorganic salts. Accordingly, another method was tried. The most
promising was a method whereby the antibiotic was salted out from the culture fluid
with ammonium sulphate; the concentrate was purified on an Al_2O_3 column, treated
with ion-exchange resins and $BaCO_3$, and evaporated in vacuo at 32-34° C. in a
stream of CO_2 . The dry substance loses its antistaphylococcal activity when stored
aerobically, but maintains it for 6 months if stored anaerobically. After salting out,
the activity of the substance increases 30-fold. During chromatographic purification
there is no change in the concentration of the preparation. The yield is 80-90%
The activity decreases after $BaCO_3$ treatment (yield 50%). After purification the
preparation strength is 65,000 U./mg. Anti-tumour activity in vitro was 0.2 µg.
ml. and in vivo 0.3 µg./ml.

~~The Hardening of Tools Made of High-Speed Steel~~
(Zakalka instrumentov iz bystrorezhushchey stali. Russian)
Stanki i Instrument, 1957, Vol 28, Nr 8, pp 38 - 38 (U.S.S.R.)

On the occasion of the heat treatment of tools with abrupt transitions of cross sections cracks often develop, as is the case with angle cutters, which are produced with diameters of from 40 - 300 mm and which differ considerably as to thickness at the periphery as well as at the opening. After heat treatment both flat cracks of a length of from 2 - 3 mm and large cracks of different lengths along the whole length of the tooth develop. Because of the complicated method of production of cutters, costs are high and waste after heat treatment amounts to up to 70 %. Investigations showed that the cracks always originate in the curvature of the outer flank of the tooth (on the outer diameter) and that the crack is smooth in the beginning but later becomes rough and similar to a fatigue crack in character. The formation of the curvatures of the tooth at both flanks is carried out by means of two different gear cutters; the greatest consumption of the gear cutters was observed to take place at the point of connection of the two surfaces when the unfinished cutters are worked and that is when it becomes blunt. As long as the gear cutter is sharp the metal is cut but as soon as it becomes blunt the metal is sheared

Card 1/2

121-8-16/22

The Hardening of Tools Made of High-Speed Steel

and torn off and the boundary layer begins to press which causes stresses and leads to the formation of cracks which are enlarged by the heat treatment. In order to avoid this disadvantage grinding of these parts (before the heat treatment) was introduced to remove the deforming upper layer of the metal. Thus the waste was completely stopped.

Periodical : Stan. 1 istr. 2, 35 - 37, Feb 1955

Abstract : Certain methods for soldering-on and thermal treatment of infusible machine tools, developed by the Metallurgical Plant "FREZER" are described. The new methods pertain mostly to the processes of soldering-on and thermal treatment of cylindrical drill bits 6 - 12 mm in diameter, conical drill bits, reamers, and countersink bores. The attachment, used for fastening tools to be soldered on, is shown in drawing. Graph; drawings.

AUTHOR: Vikin, B. P.; Perfil'yev, L. P.

TITLE: Use of a combined-coincidence gamma spectrometer in the analysis of complicated decay modes

SOURCE: Pribery* i tekhnika eksperimenta, no. 1, 1964, 53-56

TOPIC TAGS: gamma spectrometer, spectrometer, decay mode, complicated decay mode, Compton electron, Compton electron elimination

ABSTRACT: A method for the observation of a combined-coincidence spectrum for the lowest levels of nuclei having a complicated decay mode is described. An outfit of β , γ , E_γ -coincidence is offered; here, E_γ is the energy of the highest level equal to the sum of the energies of two cascade γ -quanta when that level is discharged, and β is part of the continuous beta-spectrum. The outfit permits observing only that part of the gamma-spectrum which is determined by the

Card 1/2

ACCESSION NR: AP4018363

number of recorded isotope levels. The number of levels is preselected which makes the use of a combined-coincidence gamma spectrometer possible. A spectrum of $\beta\gamma(\gamma_1 + \gamma_2)$ coincidence of $\text{Eu}^{152+154}$, was obtained with the summator aligned to the energy of the 1,124-kev level; the discriminator threshold in the beta channel was 220 kev. A spectrum with Σ , about 170 kev was also obtained. Orig. art. has: 4 figures.

Title : Excitation of ultrasonic oscillations by ponderomotive forces

Periodical : Zhur. eksp. i teor. fiz. 28, 762-764, Jun 1955

Abstract : In their work with apparatus designed to investigate nuclear magnetic resonance (DAN SSSR, 96, 1954) the authors observed at frequencies of the order of several megacycles interfering resonance effect, which as was explained arises in consequence of the excitation by ponderomotive forces of ultrasonic oscillations in the copper conductor comprising the coil of the spectrometer. They observed a number of resonance peaks, with amplitudes considerably exceeding the noise level of the device, for each of the coils during variation of the operating frequency, relative width of the peaks being equal to 1:100 in order of magnitude and the amplitude of the peaks increasing linearly with increase of the constant component and depth of modulation of the field. The authors obtained the eigenvalues of the product of the wave number times radius of the conductor by means of numerical solution of equations set up. Three references.

VINNER, D. A.

On 22 February 1946, at the Power Engineering Institute named Molotov, defended his dissertation on "Automatic Regulation of the Frequency and Active Power of Electrical Systems". Official opponents - Acting Member of the Academy of Sciences, Ukrainian SSR, Professor S. A. Lebedev, and Candidate of Technical Sciences L. S. Gol'dfarb.

So: Elektrichestvo, No 4, April 1947, pp 90-94 (U-5577, 18 February 1954)

A study was made of the basic problems of the automatic regulation of the frequency and active power in systems with synchronous turbo and hydro generators. General information was presented concerning the speed regulators of primary motors, regulation characteristics, and methods of distorting them. The method and systems of automatic frequency regulation were systematized, and descriptions were presented of some of the most widely used types of automatic frequency regulators of various firms. An examination was made of the kinetics of the process of automatic frequency regulation with the generator operating in an isolated state and with several multiple machine working in parallel, as well as the kinetics of the processes of simultaneous automatic regulation of frequency and active power in the case of two mutually interconnected electrical systems.

Title : Distribution of work hardness in the head of railroad rails

Periodical : Izv. AN SSSR, Otd. tekhn. nauk, 2, 75-78, Feb 1954

Abstract : Gives results of experiment conducted to determine depth of plastic deformation and its intensity at various distances from the top surface of railroad rails in service. X-ray structural analysis was used as a method of investigation. Table. Graphs. 6 references.

TITLE:

The resistance of diffusion coatings to the corrosion of the turbine blades of gas turbine locomotives

PERIODICAL:

Referativnyy zhurnal, Mashinostroyeniye, no. 12, 1962, 39 - 40,
abstract 12B235 ("Vestn. Vses. n.-i. in-ta zh.-d. transp.", 1962,
no. 1, 36 - 37)

TEXT:

The author presents the results of tests carried out by TsNII MPS to find methods for preventing the vanadium corrosion of the turbine blades of gas turbine locomotives. The burning of heavy liquid fuel in the gas turbine-mazout with an elevated vanadium content (up to 0.025%) causes ash depositions on the turbine blades with 60 - 75% vanadium pentoxide which, at temperatures of over 650°C, results in the rapid corrosion destruction of the blades. To prevent corrosion, a protective coating is applied to the blade surface by the diffusion metallization method. Coatings were tested which were applied by aluminum siliconizing, calorizing, chrome plating and siliconizing. It is pointed out that chrome-
